CREATIONAL PATTERNS

DESIGN PATTERNS | GoF

ABSTRACT FACTORY

programm
client
class fabric 1
interface product A
class product A1
create product A1
class fabric 1
class product B1
create product B1
interface abstract fabric
class fabric 2
class product A2
create product A2
class fabric 2
interface product B
class product B2
create product B2

In the whole program (except for the factory inside and one factory creation) we work only with interfaces (and do not refer to specific classes)
programm
create concrete fabric class
use fabric
use products
work throught interface
work throught interface
interface product A
interface abstract fabric
interface product B
When you start the program in the main method, create all factories – this isolates the creation of all specific dependencies in one place
Isolate all dependencies to specific classes in one place
main method (start program)
create fabric
class fabric 1
create product A1
create product B1
class product A1
class product B1

BUILDER

programm
create subclass builder
create director and put inside builder
construct some object
get specific result A
new constructed complex object
select result product view:
builder A or builder B
(for example select A)
instance A
new DIRECTOR(instance A)
instance of class A
subclass builder A
getResult A
build part 1
build part 2
build part 3
subclass builder B
getResult B
build part 1
build part 2
build part 3
provides a generic/simplified interface for the build / construct another complex object
class director
construct algoritm
step
step
work throught interface
interface builder
build part 1
build part 2
build part 3

programm
product
subclass builder A
getResult A
subclass builder A
build part 1
class director
class director
builder
construct algoritm
for each objects in structure
{
builder->build part 1
}
interface builder
interface builder
build part 1

FACTORY METHOD

programm
class creator
class creator
ABSTRACT fabric method
construct algoritm
product = fabric method ()
interface product
interface
product
subclass creator A
subclass
concrete creator
A
fabric method
return new Concrete product A
subclass product A
subclass
concrete product
A

PROTOTYPE

programm
create subclass proto
create client
construct some object
select: algo work on proto A or B (for example select A)
instance A
new PROTOTYPE(instance A)
instance of class A
meaning in the creation of instances by cloning
subclass prototype A
clone
method 1
method 2
method 3
subclass prototype B
clone
method 1
method 2
method 3
class client
construct algoritm
clone instance
step on new instance
step on new instance
interface prototype
clone
method 1
method 2
method 3

programm
subclass prototype A
clone
return copy(self)
subclass
prototype A
subclass prototype B
clone
return copy(self)
subclass
prototype B
class client
class client
prototype
construct algoritm
p = prototype -> Clone ()
interface prototype
interface
prototype
clone

SINGLETON

programm
first access to singleton
second access to singleton
class singleton
only one instance exists
constructor disallowed
singleton instance
get instance (method of the class)
create instance and return
instance =null
get var
return instance already exists

programm

class singleton
class singleton
singleton instance
get instance (method of the class)
static method
{
return static singleton instance
}

STRUCTURAL PATTERNS

DESIGN PATTERNS | GoF

ADAPTER OF CLASS

programm
client
interface adapter
interface
adapter
(target)
method 1
inherit
class adapter
class adapter
method 1
method 2 ()
inherit
class adaptee
class adaptee
method 2

ADAPTER OF OBJECT

programm
create adapter
call known method 1
work throught interface
work throught interface
interface adapter
interface adapter (target)
method 1
inherit
class adapter
class adapter
constructor
create adaptee
method 1
call SUPER(adaptee).method 2
class adaptee
class adaptee
method 2

programm
client
interface adapter
interface
adapter
(target)
method 1
inherit
class adapter
class adapter
adaptee
method 1
adaptee -> method 2 ()
class adaptee
class adaptee
method 2

BRIDGE

programm
create some abstraction and put some implementator inside
use some method
work throught interface
method call through the two inheritance hierarchy and a link between the hierarchies
- for example, call some methods of the class A
- wich leads to invoke methods of the class C
interface abstraction
work throught interface
<constructor> or some method
get or create instane
VAR instance implementator (C or D)
method 1
method 2
BRIDGE
interface implementator
method 3
method 4
method 5
class refined abstraction A
work throught methods of interface
method 1
use method 4
use method 5
method 2
use method 4
use method 3
class concrete implementator C
method 3
method 4
method 5
class refined abstraction B
method 1
use method 3
use method 4
method 2
use method 4
use method 4
class concrete implementator D
method 3
method 4
method 5

programm
client
interface abstraction
interface abstraction
imp
method 1
imp-> method 3
interface implementator
interface implementator
method 3
class abstraction A
class refined abstraction A
class implementator C
class concrete implementator C
method 3
class implementator D
class concrete implementator D
method 3

COMPOSITE

programm
create composite
if
getComposite<>NULL
leaf create&add
to composite
some operation on
composite
work throught interface
work throught interface
example:
full tree component instances
(leafs and composites)
composite
consist of
leaf
composite
leaf
the instance of the class
interface component
VARIABLE: list of instances of COMPONENT type (LEAF or COMPOSITE)
composite relation (var
of interface
COMPONENT type)
operation 1
getComposite
add(component)
remove(component)
getChields()
class composite
VARIABLE: list of instances of COMPONENT type
leaf
leaf
composite
operation 1
for each list
member
call operation
on each list
getComposite
return SELF
add(component)
add
component to
list
remove(component)
remove
component
from list
getChields()
get
components
list
class leaf
operation 1
some
operation on
leaf
getComposite
return NULL
add(component)
remove(component)
getChields()

programm
client
interface component
interface component
operation 1
add(component)
remove(component)
getChields()
descendants
class leaf
class leaf
operation 1
class composite
class composite
operation 1
for each descendants i
{
i . operation 1 ( )
}
add(component)
remove(component)
getChields()

DECORATOR

programm
some operation on decorator B(through all tree)
create decorator B
add decorator A inside
create decorator A
add concrete component inside
create concrete component
example:
full sequence component instances
(concret component and decorators)
provide additional functional to another object
interface component
VARIABLE to some interface COMPONENT type
composite relation (var of interface COMPONENT type)
constructor
operation 1
operation 2
class decorator (ADDITIONAL functionality)
VARIABLE to some interface COMPONENT type
constructor
VAR=some COMPONENT
operation 1
call VAR.operation 1
operation 2
some operation on component
class concrete decorator B
VARIABLE to some interface COMPONENT type (copy)
instance of recorator A
operation 1
enhance functional of operation 1
call superclass.operation 1
connect of
class concrete decorator A
VARIABLE to some interface COMPONENT type (copy)
instance of concrete component
operation 1
call superclass.operation 1
enhance functional of operation 1
class Concrete Component (BASE functionality)
VARIABLE to some interface COMPONENT type (copy)
constructor
receive and store some DATA
operation 1
some operation on DATA
operation 2
some operation on DATA

interface component
interface component
operation 1
composite relation
component
class Concrete Component
class Concrete Component (BASE
operation 1
class decorator
class decorator (ADDITIONAL functionality)
operation 1
component -> operation 1 ( )
class concrete decorator A
class concrete decorator A
operation 1
class decorator
class concrete decorator B
added behavior
operation 1
decorator::operation 1 ( ); added behavior ( );

FACADE

programm
call facade methods
access between the layers only through facades
layer 1 (subsystem/module/package)
facade 1
use some methods of classes
class A
class B
class C
facade created absolutly new interface
- only one point (class/interface)
- simplified (short)
- default
- common
- for most frequent cases
if I want use all possibilities, I use directly all classes
one-way calls. facade sends requests subsystem classes
access between the layers only through facades
layer 2 (subsystem/module/package)
facade 2
You can change the inner layer classes without fear affects other layers
use some methods of classes
class D
class E
class F
antipattern: if the facade is a class (not an interface) then all clients will transitively depend on all classes behind the facade
access between the layers only through facades
layer 3 (subsystem/module/package)
facade 3
use some methods of classes
class G
class H
class J

class A
access between the layers only through facades
module/package
facade 2

facade class
the facade for convenience combines / exposes the diverse functionality that other classes provide
func1
func2
func3
ref to class1
ref to class2
ref to class3
each class has its own responsibility
class1
func1
class2
func2
class3
func3

FLYWEIGHT

programm
create flyweight
create flyweight (the same)
create context
some operation on composite with context
work throught factory
class factory
shares a small number of object instances
dictionary (key=inner shared state ,value=ref to shared instance)
get or create shared flyweight (input = inner shared state)
get instance already exists from dictionary
get
create
create concrete flyweight with given inner shared state
write instance into dictionary
create unshared concrete flyweight
class context (outer unshared state)
get info attrs for some element in tree
interface flyweight
operation 1 (outer unshared state)
class UnsharedConcreteFlyweight
operation 1 (outer unshared state)
class concreteFlyweight
inner shared state
operation 1 (outer unshared state)
get additional info from context
some operation on leaf

programm
client
class factory
class factory
flyweights
get or create shared flyweight (Input = inner shared state)
IF flyweights[key] exists
{
return flyweight[key]
}
else
{
create new flyweight
add to flyweights
return new flyweight
}
interface flyweight
interface flyweight
operation 1 (outer unshared state)
class concreteFlyweight
class concreteFlyweight
inner shared state
operation 1 (outer unshared state)
class UnsharedConcreteFlyweight
class UnsharedConcreteFlyweight
operation 1 (outer unshared state)

FLYWEIGHT + COMPOSITE

PROXY

programm
create proxy
call cheaper method 2
call real method 1 through the proxy
work throught interface
interface of subject
dont think about cheaper or real
method 1
method 2
inherit
inherit
class proxy
this is the replace of another object
REF to real subject
method 1 (require real object data)
get REAL instance already exists
REF exists
call some real object method
create REAL instance
REF == 0
write instance into REF
method 2 (get fake data)
call method on instance already exists
REF exists
REF == 0
return some fake data
class real subject
method 1
method 2

programm
client
interface subject
interface of subject
method 1
inherit
inherit
class proxy
class proxy
real subject
method 1 (require real object data)
real subject -> method 1
class real subject
class real subject
method 1

BEHAVIORAL PATTERNS

DESIGN PATTERNS | GoF

CHAIN OF RESPONSIBILITY

programm
client
class concrete handler A
class concrete handler A
handle request
class handler
class handler
handle request
class concrete handler B
class concrete handler B
handle request

COMMAND

separation of the invoker and recipient by the command
programm
create receiver
create command
put receiver inside
create invoker
put command inside
programm
invoke receiver
class receiver
action
interface command
constructor
execute
class invoker
constructor (COMMAND)
store reference in VAR
REF to COMMAND
on click
call VAR.execute
class concrete command
constructor (RECEIVER)
store reference in VAR
REF to RECEIVER
execute
call VAR.action

programm
client
class receiver
class receiver
action
interface command
interface command
execute
class invoker
class invoker
receiver
class concrete command
class concrete command
execute
receiver - > action ( )

INTERPRETER

programm
client
Group
interface abstract expression
interface abstract expression
interpret (CONTEXT)
composite relation
class terminal expression
class terminal expression
interpret (CONTEXT)
class NONterminal expression ||
class NONterminal expression ||
interpret (CONTEXT)

ITERATOR

programm
traversal algorithm in a separate class
get iterator from aggregate
next item in iterator
if not end
some operation on get item
interface aggregate
create iterator
return iterator
aggregate use interface iterator
interface iterator
constructor (AGGREGATE)
first
next
is Done
current item
REF to aggregate
iterator has a link to interface aggregate
subclass concrete aggregate A
create iterator
create concrete iterator A (this)
return iterator
subclass product concrete iterator A
constructor (AGGREGATE)
set REF=input parameter
first
set POSITION=0
REF to aggregate
current position
next
POSITION++
is Done
IF POSITION >= REF.count return TRUE
current item
return REF[POSITION]
subclass concrete aggregate B
create iterator
create concrete iterator B
return iterator
subclass product concrete iterator B
constructor (AGGREGATE)
set REF=input parameter
first
set POSITION=0
REF to aggregate
current position
next
POSITION++
is Done
IF POSITION >= REF.count return TRUE
current item
return REF[POSITION]

programm
client
interface aggregate
interface aggregate
create iterator
interface iterator
interface iterator
first
next
is Done
current item
subclass concrete aggregate A
subclass concrete aggregate A
iterator has a link
create iterator
return new Concrete Iterator (this)
subclass product A
subclass product concrete iterator A
aggregta use iterator

MEDIATOR

programm
create mediator and colleagues
interface mediator
create colleagues
colleague changed (COLLEAGUE)
interface colleague
REF to mediator
constructor (MEDIATOR)
store input as VAR
changed
mediator.colleague changed (this)
two-way calls.
- colleague sends requests to mediator
- mediator send request to collegues
- Colleagues are not linked directly
- centralized exchange: the whole algorithm in the mediator
class concrete mediator
REF to A
ref to B
create colleagues
create colleague A (this)
create colleague B (this)
colleague changed (COLLEAGUE)
do some on A
do some on B
class concrete colleague A
event 1
constructor (MEDIATOR)
method 1
class concrete colleague B
event 2
constructor (MEDIATOR)
method 2

interface mediator
interface mediator
mediator
interface colleague
interface colleague
class concrete mediator
class concrete mediator
class concrete colleague A
class concrete colleague A
class concrete colleague B
class concrete colleague B

MEMENTO

- state of originator has changed
- and must be restored to its original state
caretaker
save state of originator
some operation on originator witch changes state
load saved state of originator
REF to memento
class originator
state O
create memento
set state M of memento (VAR)
return memento
set memento (MEMENTO)
get state M of memento
set VAR
class memento
state M
set state(STATE O)
set VAR=input
get state
return VAR
- state is stored in a separate object
- the client can only store REF to memento
- Only the owner can change memento (call methods)

caretaker
caretaker
memento
class originator
class originator
state O
create memento
return new
Memento (state)
set memento
(MEMENTO)
state = memento ->
get state ()
class memento
class memento
state M
set state(STATE O)
get state

OBSERVER

programm
now states of observer and object automaticaly synced
set state of concrete object
create subject and attach observer
create observer
decentralized sharing subject can be an observer
interface subject
attach (OBSERVER)
ARRay of OBSERVERS
REF to observer 1
REF to observer 2
REF to observer 3
detach (OBSERVER)
notify ()
for each observers
REF . update(this)
interface observer
update (SUBJECT)
class concrete subject
get state
return subject state
set state (some data)
set subject state = some data
call notify
subject state
interface concrete observer
update (SUBJECT)
get subject . state
set observer state = subject . get state
observer state
states syncing (subject state and observer state)

interface subject
observers
interface subject
attach (OBSERVER)
detach (OBSERVER)
notify ()
for each observers
{
observer -> update ( )
}
interface observer
interface observer
update (SUBJECT)
class concrete subject
class concrete subject
get state
return subject state
set state (some data)
subject state
subject
interface concrete observer
interface concrete observer
update (SUBJECT)
observer state = subject - > get state ()
observer state

STATE

programm
some request
some request
- the state itself is also able to switch the current state
- current behavior depends on the current state (pre-history).
- behavior changes at runtime
for example:
- now we are in state A
- and we will change to state B
class context
interface state
REF to state object (interface state type)
- instead multiple IF only in one place
- context or state can change REF(to current state)
method 1
method 2
request 1
use method 1
DECISION TO CHANGE STATE
use method 2
class concrete state A
request 2
change state to A
use method 2 of REF current state
DECISION TO CHANGE STATE
change state to B
use method 2 of REF current state
method 1
method 2
change state (state object)
create state A or B
set REF to created state as current state
class concrete state B
method 1
method 2

class context
class context
state
request 1
state -> method 1
interface state
interface state
method 1
class concrete state A
class concrete state A
method 1
class concrete state B
class concrete state B
method 1

STRATEGY

programm
create subclass strategy
create context, and put inside startegy
call method
select algo:
strategy/algo A
or
strategy/algo B
for example, select A
instance A
new STRATEGY(instance A)
instance of class A
class concrete strategy A
some algoritm (some data)
step
step
return some result
class concrete strategy B
some algoritm (some data)
step
return some result
class context
context interface
call algoritm on strategy instance
work throught interface
interface startegy
some algoritm (some data)

class concrete strategy A
class concrete strategy A
some algoritm (some data)
class concrete strategy B

data A
class concrete visitor 1
class concrete visitor 1
visit Concrete Element A (CONCERTE ELEMENT A)
visit Concrete Element B (CONCERTE ELEMENT B)
class concrete element B
class concrete element B
accept(VISITOR)
VISITOR -> visit Concrete Element B (this)
data B
class concrete visitor 1
class concrete visitor 1
visit Concrete Element A (CONCERTE ELEMENT A)
visit Concrete Element B (CONCERTE ELEMENT B)

programm
create object structure
create elements and add to object structure
create visitor 1
visit allobjects
select algo: visitor 1 or visitor 2 (for example select visitor 1)
instance visitor 1
place concrete visitor as input parameter
The new operation is created by adding a subclass Visitors to the hierarchy of classes
class object structure
iterate (VISITOR)
for all objects in ARR
call accept for each element with some visitor
the visitor can visit the objects/ classes of ANY types
ARR of concrete elements
REF to A
REF to A
REF to B
REF to B
interface element
accept(VISITOR)
interface visitor
visit Concrete Element A (CONCERTE ELEMENT A)
visit Concrete Element B (CONCERTE ELEMENT B)
class concrete element A
accept(VISITOR)

DATA MAPPER

presentation
domain
some process
update 1 object
change some object some properties for update
some business logic on object
find some data objects
class type 1
properties (corresponds to table columns)
some business logic function 1
some business logic function 2
class type 2
class type 3
object of class type 1
the object is parameter of method call
the object is return value of method call
instance of class type 1
data source
Fowler elementary pattern: mapper
- A separate class for mapping data
- The domain class and the class of the data source does not depend on the mapper
- Mapper is used as an insulator
class mapper 1
Create/insert (v_object)
SQL insert 1 empty row
call update
Read(id)
SQL select 1 row statement
return object of type `class type 1`
Update (v_object)
get props from v_object for use in update
SQL update 1 row statement
Find(parameters)
SQL select rows statement
return array of objects of type `class type 1`
query results transmitted to the factory, and it returns an object
Delete (id)
get id
SQL delete 1 row statement
factory (props)
create obj and fill properties acording with input args
return created object of type `class type 1`
class mapper 2
class mapper 3
database
entity 1
entity 2
entity 3
entity -relationship model

IDENTITY MAP

LAZY LOAD

presentation
domain
data source
sequence of operations
Create object
Read object or Find (enough use the fake)
call some fake methods
Read object or Find (need real data)
call real methods
Update object
Delete object
GoF pattern: proxy or state
class with lazy load
real object class
loading objects only when required actual data
method 1 (require real object data)
get instance already exists
instance already exists
create instance
access to DB
call some real object method
method 1
method 2 (get fake data)
instance already exists
call method on instance already exists
return some fake data
method 2
database
entity 3
entity 2
entity 4
entity 1
entity 6
entity 5

UNIT OF WORK.

presentation
create session
some operations
end session
domain
sequence of operations
Create object
Read object or Find
Update object
Delete object
COMMIT all operations
- all jobs (requests) are a single transaction, which is called 'unit of work'
- Transaction management method
read and finders without unitOfWork
some data source classes, through which to access the database
class unit of work
GoF pattern: pattern
array of works
SQL insert statement object in arr
SQL update statement object in arr
SQL delete statement object in arr
Create/insert (v_object)
add SQL query to array
Update (v_object)
add SQL query to array
Delete (id)
add SQL query to array
commit
loop for all task in array
exec SQL query
clear array
Only commit writes to the database
one package or transaction to DB
database
entity 3
entity 2
entity 4
entity 1
entity 6
entity 5

REPOSITORY

presentation
domain
some process
find operation
class type 1
property A
property B
some relations
class type 2
property C
property D
class type 3
property E
property F
data source
client works with objects as if they are located in the usual array.
Fowler: query object, DDD: repository GoF: facade
collection
In the example, a common interface is used that provides all the CRUD operations.
In practice, a specific interface can be used (providing its own set of operations with its own names), which makes sense only for the given domain.
repository 1 (Subtype of collection)
array of objects of class type 1
add object to array (object)
get object from array(index)
update object in array(index,object)
get filtered array(criteria)
delete object from array(index)
Repository 2
array of objects of class type 2
add object to array (object)
get object from array(index)
update object in array(index,object)
get filtered array(criteria)
delete object from array(index)
Repository 3
array of objects of class type 3
add object to array (object)
get object from array(index)
update object in array(index,object)
get filtered array(criteria)
delete object from array(index)
Fowler: query object
instance of query object (for example, class type 1)
criteria (for example, property A= 'hello')
class query object
class type name
array of criterias
class criteria
class property name
propery value
Fowler: mapper
class mapper 1
Create/insert (v_object)
Read(id)
Update (v_object)
Find(query object)
Delete (id)
SQL:
select *
from entity 1
where column A = 'hello'
class mapper 2
Create/insert (v_object)
Read(id)
Update (v_object)
Find(query object)
Delete (id)
factory (props)
class mapper 3
Create/insert (v_object)
Read(id)
Update (v_object)
Find(query object)
Delete (id)
factory (props)
database
entity - relationship model
entity 1
column A
column B
entity 2
column C
column D
entity 3
column E

SERVER SESSION STATE

COMMON PATTERNS

ENTERPRISE PATTERNS

Martin Fowler

GATEWAY

- a wrapper of classes that simplifies access it from the CLIENT 1
- not too simplifying to all possible clients (as in the facade pattern)
- And not adapting one class to another (as in the adapter) because both sides are developed at the same time
some layer 1
client 1
call gateways
some layer 2
gateways (GoF: facade, adapter, mediator)
class gateway A
class gateway B
class gateway C
class A
class B
class C

LAYER SUPERTYPE

MAPPER

layer 1
classes 1
- translate messages of
classes 1 type
to messages of
classes 2 and vice versa
- unlike the mediator does not
control the interaction between
the systems but simply translates
the requests and responses,
transforming message formats
some message of
type 1
layer 2 (GoF pattern: mediator) (Fowlers pattern: gateway)
mapper
some message of
type 2
layer 3
classes 2

MONEY

- special class for the money, taking into account currency
- the numerical value of money itself is stored in integer format (LONG)
class currency
currency
get default fraction digits
Currency Converter
class money
amount LONG
REF to currency
operations
+ (money object)
check that the money in the same currency
return Money (this.amount +moneyObj.amount)
- (money object)
check that the money in the same currency
return Money (this.amount - moneyObj.amount)
* (bigdecimal, rounding mode)
return Money (this.amount *moneyObj.amount, currency,rounding mode)
allocate(proportions X:Y:Z)
find $,$,$ where $:$:$=X:Y:Z and $+$+$=amount
money left over after rounding distributed between all parts of the proportion $:$:$ of randomly
return $,$,$
compare
>
<
>=
<=
compare (money object)
check that the money in the same currency
if this.amount>object.amount
return true
else return false
compare (some object)
call
constructors and fabrics
construnctor (amount, currency obj)
amount *10^currencyObj.getDefaultFractionDigits
fabric for dollars (amount)
return Money(amount, Currency.USD)
amount()
return amount *10^(-currencyObj.getDefaultFractionDigits)
equal
equals (some object)
validate that object of Money type
some object EQUAL this
equals (money object)
validate that object.currency EQUAL this.currency
validate that object.amount == this.amount
hashCode ()
return (int) (amount ^ (amount >>> 32))

PLUGIN

GoF pattern: bridge
- It will automatically create an instance of the desired subclass (specified in the configuration file)
-plugin is determined dynamically
- during a properties file reading
- during a call supertype constructor
some process
create supertype
call some func
Fowler pattern: separated interface, gateway
separated interface
constructor
get object
some func
plugin 1
class implementation 1
some func
plugin factory
plugin factory
get plugin
get current configuration
create an instance of class by class name
plugin 2
class implementation 2
some func
properties file
current plugin class name
for example, current plugin = class implementation 1

RECORD SET

presentation
domain
data source
class corresponds to the table with strings
class record set
array of objects of class record
get object from array(index)
get filtered array(criteria)
class corresponds to a row of the table
class record
property A
property B
database
entity -relationship model
entity 1
column A
column B

REGISTRY

some layer
find some objects of class 2
get registry
(one for all)
get finder
find
GoF patern: singleton
Registry
ref to finder 1
ref to finder 2
ref to finder 3
class1 finder
Find (ID)
return object
of class 1
class2 finder
Find (ID)
return object
of class 2
class3 finder
Find (ID)
return object
of class 3
class 1
class 2
class 3
Access to the global data and
functions (for example, find domain
objects)

Domain Driven Design

Tackling Complexity in the Heart of Software.

ERIC EVANS

MODEL AND STRUCTURAL ELEMENTS

DOMAIN DRIVEN DESIGN

Eric Evans

MODEL-DRIVEN DESIGN

Conceptual domain model (business layer)
entity 1
1 : N
entity 2
model driven design
Domain model (information systems: application layer)
class 1
the Class 1 contains an array of references to the class 2
class 2
Data model (information systems: data layer)
table 1
the Table 2 contains the foreign key to the Table 1
table 2

Single responsibility principle from the SOLID model
Conceptual domain model (business layer)
Business Actor 1
Business Actor 2
If we go to the cause of class changes – those to the business customer, it turns out that each class is associated with one such 'person'. This is due to Conway's law that the structure of the program reflects the structure of the organization.
Domain model (information systems: application layer)
class 1
class 2

LAYERED ARCHITECTURE (ASYMMETRIC)

variant 1

variant 2

HEXAGONAL ARCHITECTURE (SYMMETRIC)

the direction of all dependencies (inheritance or challenges) is strictly towards the center, there are no other directions and there are absolutely no cyclic dependencies
user
infrastructure / presentation layer
input adapter
application service layer
application service
domain layer
domain model
system 1
output adapter
application service
application service
input adapter
system 2
application service
output adapter
database

application service layer
input adapter
it is shown how to receive calls from dependent modules and transfer calls to dependent modules
domain layer
domain model
receiver
method1
Interface
method1
caller
method call
Interface
method2
Value-object
output adapter
input adapter
caller
The lower-level classes do not call the upper-level classes directly, but through a protective interface (which hides the features of the main-level implementation)
method call
some class
some va
lower levels freely use DTO, Value-objects defined on the upper level
output adapter
Implementation / receiver
method2
lower level classes implement upper level interfaces.
see patterns: Separated Interface, Dependency Inversion

application service layer
input adapter
the high-level component itself actively controls the interaction of low-level components. In this case, the logical flow of data (information from the input adapter to the receiver) and dependencies(the receiver actively polls the adapter itself) in opposite directions.
domain layer
domain model
receiver
Interface
method1
method call
caller
method call
Interface
method2
input adapter
Implementation / caller
method1
output adapter
lower level classes implement upper level interfaces.
see patterns: Separated Interface, Dependency Inversion
output adapter
Implementation / receiver
method2

COMPOSITE UI

ENTITIES

Conceptual domain model (business layer)
entity 1
Domain model (information systems: application layer)
The main thing that separates an Entity from other modeling tools is its uniqueness - its individuality
class 1
id
Identifier unchanged for the object
identity in the domain
unique value within the domain
equals (object of class 1)
Compare that identifiers are equal
when comparing objects, you compare the type and the ID (Instead of comparing pointers or object references)
The identifier itself is implemented as an object-value
equals (some object)
check that the object of type class 1
attributes
Entities are mutable as the other attributes can change but its unique identity won't change once it is set

class entity factory 1
static factory method (params)
generate GUID
return new instance of entity 1 with ID=GUID
For absolutely new instances
static factory method (ID and params)
return new instance of entity 1 with given ID
For recovered from persistence instances
class entity 1
ID
attributes
check invariant 1 (param3, param4)
check rule 1 (param 1, param2)
validate (params)
constructor (params)
validate input params
set attrs
ref to spec
check rule 3 ()
call specification 1(this)
class specification 1
check invariant 2 (object of class 1)
return bool

VALUE-OBJECTS

See example: Fowler's Money
value object
Get Attributes To Include In Equality Check ()
equals (object of value type 1)
Compare that attributes are equal
equals (some object)
check that the object of type value type 1
= (object 1, object 2)
!= (object 1, object 2)
GetHashCode()
class value object 1
attributes
Get Attributes To Include In Equality Check ()
check rule 2 (param 3, param4)
check rule 1(param 1, param2)
validate(params)
Integrity check
static factory method (params)
validate input params
return new instance of value type 1
+ (object 1, object 2)
return new instance of value type 1
- (object 1, object 2)
return new instance of value type 1
* (object 1, object 2)
return new instance of value type 1
/ (object 1, object 2)
return new instance of value type 1
Combination of objects

DOMAIN SERVICES

Domain model (information systems: application layer)
Example of communicating services with aggregates via direct service call
class entity 1
ref to service 1
check()
call check(this)
Interface service 1
test (instance of entity 1)
class service 1
check (instance of entity 1)

Services support each other

Example of communicating services with aggregates through events
aggregate 1
event C
event A
aggregate 2
service 3
event B

UI layer
event from UI
MyController
someMethod
Business-logic layer
MyService
do(String id,int amount)
domain model
MyServiceImpl
do(String id,int amount)
my=repository.getMyById(id)
my.do(amount)
reference to repository
My
do(int amount)
MyService-MyServiceImpl and MyRepository-MyRepositoryImpl is a Bridge-pattern
data-access layer
MyRepository
getMyById(String id)
MyRepositoryImp

MODULES

Domain model (information systems: application layer)
In order to reduce the complexity of the domain model, the program is divided into modules.
module 1
high cohesion inside module
module 2
high cohesion inside module
low coupling between modules
module 3
high cohesion inside module

AGGREGATES

Must satisfy the invariants 1
When removed, everything inside the aggregate is eliminated
aggregate 1
The aggregate consists of entities and value objects.
The aggregate forms a transactional consistency boundary supported by invariants.
Aggregates should be based around invariants.
class 1
class 2
class 3
aggregate 2
Must satisfy the invariants 2
class 4
class 5
class 6
aggregate 3
class 7
class 8
class 9
Must satisfy the invariants 3

In the course of modeling, think about different ways of splitting the model into aggregates

AGGREGATE ROOT

BEHAVIOR-FOCUSED AGGREGATE ROOT

MODIFY AND COMMIT ONLY ONE AGGREGATE INSTANCE IN ONE TRANSACTION

PROTECT BUSINESS INVARIANTS INSIDE AGGREGATE BOUNDARIES

REFERENCE OTHER AGGREGATES BY IDENTITY ONLY

FACTORIES

application service layer
Use factory to create aggregates, complex entities and value objects.
Use factory to re-create domain objects from persistent storage.
The factory creates an aggregate entirely, with the satisfaction of all invariants
GoF pattern: factory
class factory 2
recreate aggregate with given ID and params
create new aggregate 2 and return aggreagate root
domain layer
Must satisfy the invariants 2 after creation
aggregate 2
The root of the aggregate itself creates all internal objects
class
class 5
class 6

class entity factory 1
static factory method
Select a specific subtype of the object to be
The factory requires some deeper knowledge of the domain to select the correct type of instance
class entity A1
constructor (params)
class entity A2
constructor (params)
class entity A1
constructor (params)
interface A

REPOSITORIES

domain
aggregate
aggregate root
PRIVATE constructor (snapshot)
PUBLIC static factory method (snapshot)
PUBLIC get snapshot ()
GoF pattern: memento
application
repository
FindBy (params)
get data from database
transform data to snapshot
put snapshot to aggregate
add(params)
get snapshot from aggregate
transform snapshot to data
put data into database
infrastructure
database

domain
Fowler's patters: optimistic lock
entity
application
repository
update aggregate in array
(index,aggregate)
check current aggregate's
version and version from DB
if <> throw
exception
increment the version number
commit
infrastructure
entity
version
The version attribute is not a
domain attribute

domain
model
entity
abstract Entity
id
name
abstract BaseEntity
isModified
class Booking
restaurantId
userId
tableId
value
BookingVO
repository
interface ReadOnlyRepository
contains
get
getAll
interface Repository
add
remove
update
interface BookingRepository
containsName
findByName
class InMemBookingRepository
Booking[Map] entities
@Repository("bookingRepository")
Bridge Pattern: abstract class has a reference to Repository interface
also Bridge Pattern: abstract class has a reference to Repository interface
service
abstract ReadOnlyBaseService
ReadOnlyRepository repository
abstract BaseService
Repository _repository
add
getAll
interface BookingService
add
update
delete
findById
findByName
findByCriteria
It's seens that the method the same (as in repository) but acording with Bridge Pattern, now I can change it seperately
class BookingServiceImpl
bookingRepository
@Service("bookingService")
controller
class BookingController
@Autowired bookingService
findByName
exception if not found

SUPPLE DESIGN

DOMAIN DRIVEN DESIGN

Eric Evans

UBIQUITOUS LANGUAGE

INTENTION-REVEALING INTERFACES

SIDE-EFFECT FREE FUNCTIONS

ASSERTIONS

assertion defines the result of an operation or an invariant
Application Component
command with side effects
Conditions that must be met, so that the post-condition gives a guaranteed result
test command
assert pre-conditions
Explicit record of assertions, helps the developer to understand the work of the command and side effects
call command
The side effects of the operation are the guaranteed consequences of calling the method
assert post-conditions

DEPENDENCY INJECTION

the diagram demonstrates the basic concepts of DI:
- the main component
- root of composition
- recognition root - first recognized and injected class (the root of the object graph to be recognized)
Application
the main component
- it provides only the workability of the system .
- his task is to create all Factories, Strategies and other global tools and then transfer control to high-level abstractions in the system .
- it is in the main component that all dependencies should be implemented using the dependency injection infrastructure
main method
Composition root
create and run container
ref to controller
Controller
Recognition root
reference to service
constructor(ref to service)
DI container also Inject Dependency to the service instance (find appropriate class and create instance before it)
Service
DI Container
find all the appropriate controller classes, select the most appropriate one, create a controller instance, and implement the dependency on that instance

DEPENDENCY INVERSION
